

Deep Learning Seminar Day-3

Master of Science in Signal Theory and Communications
TRACK: Signal Processing and Machine Learning for Big Data

Prof. Luis A. Hernández Gómez luisalfonso.hernandez@upm.es

Departamento de Señales, Sistemas y Radiocomunicaciones E.T.S. Ingenieros de Telecomunicación Universidad Politécnica de Madrid

Modelling sequences

- Applications areas are broad:
 - Signals: video, speech, sensors,....

Time series: financial series, log messages,...

Sequence of characters: Natural Language Processing,...

Sequences of observations, actions, rewards: Reinforcement
 Learning (robots, bots, autonomous vehicles, dialog
 systems..)

Is it always necessary to use dynamic/memory models?

You can see Human Activity Recognition examples at:

https://github.com/MasterMSTC/DeepLearning_TF_Keras

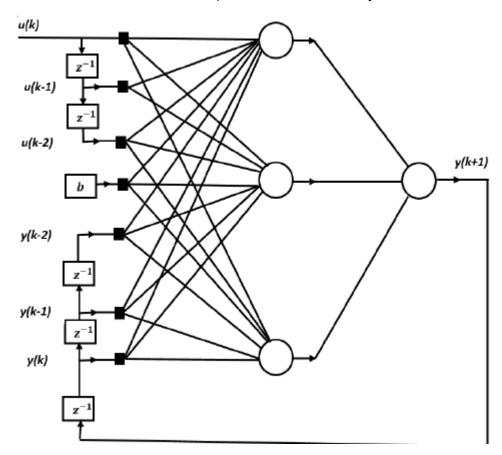

MSTC_HAR_CNN_2018.ipynb

MSTC_Keras_HAR_CNN_2018.ipynb

Memoryless models for sequences

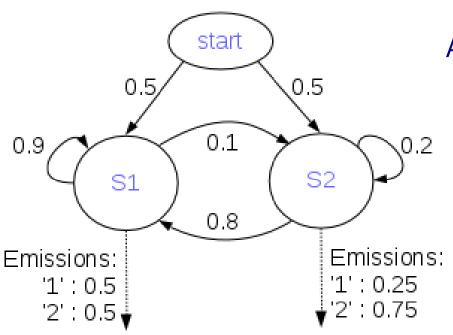

- NARX model: Nonlinear Auto Regressive Model with external inputs.
- Another name: TDNN (time-delay neural network)

Dynamic Generative Models: as for example Hidden Markov Models

- Hidden Markov Models have a discrete one-of-N hidden state.
- Transitions between states are stochastic and controlled by a transition matrix.
- The outputs produced by a state are stochastic.

A fundamental limitation of HMMs

- Consider what happens when a hidden Markov model generates data.
 - At each time step it must select one of its hidden states.
 - So with N hidden states it can only remember log(N) bits about what it generated so far.

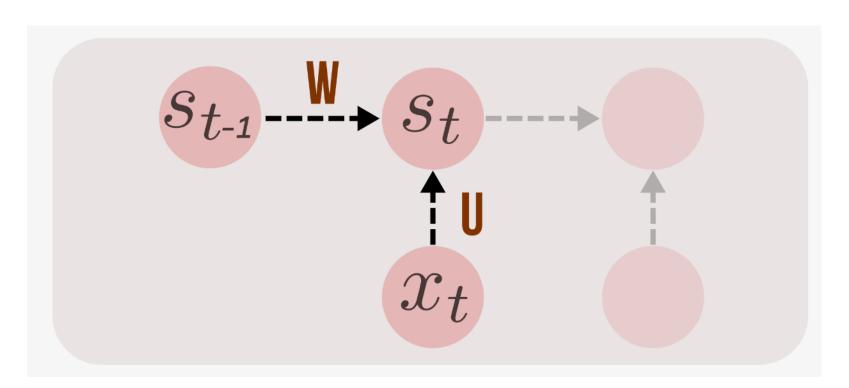

From: Geoffrey Hinton

CSC2535 2013: Advanced Machine Learning

Recurrent Neural Networks (RNN)

• RNNs combine the **input vector** with their **state vector** with a fixed (but learned) function to **produce a new state vector**.

$$s_t = tanh(Ux_t + Ws_{t-1}),$$

Recurrent Neural Networks (RNN)

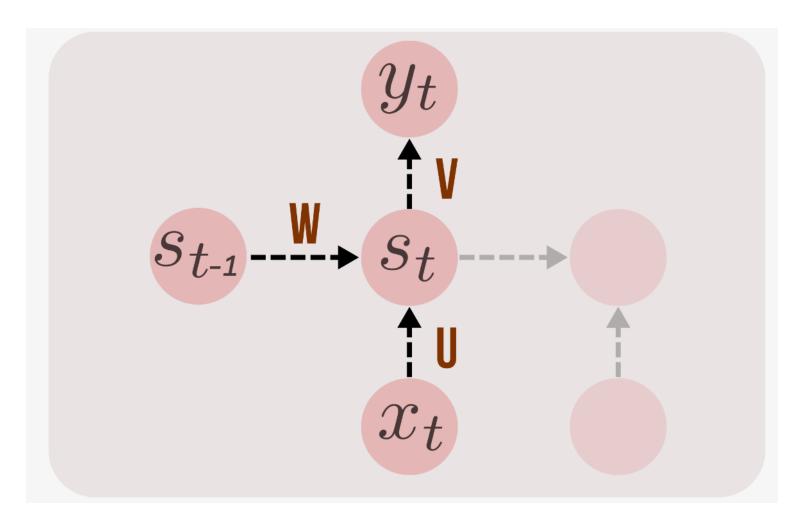

- RNNs are very powerful, because they combine two properties:
 - Distributed hidden state that allows them to store a lot of information about the past efficiently.
 - Non-linear dynamics that allows them to update their hidden state in complicated ways.
- With enough neurons and time, RNNs can compute anything that can be computed by your computer.

From: Geoffrey Hinton

CSC2535 2013: Advanced Machine Learning

OUTPUT y_t logits = tf.matmul(state, V) + b
predictions = tf.nn.softmax(logits)

RNN essentially describe programs:

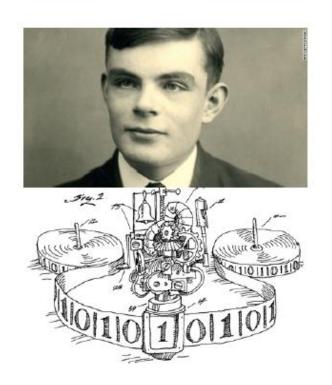

inputs + some internal variables.

In fact, it is known that RNNs are Turing-Complete in the sense that they can to simulate arbitrary programs (with proper weights).

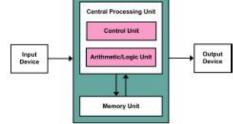

Neural Turing Machines

Can neural nets learn programs?

Translating Videos to Natural Language Using Deep Recurrent Neural Networks Subhashini Venugopalan, et al.

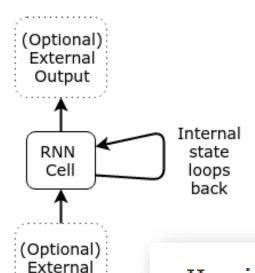

Written Memories: Understanding, Deriving and Extending the LSTM

http://r2rt.com/written-memories-understanding-deriving-and-extending-the-lstm.html

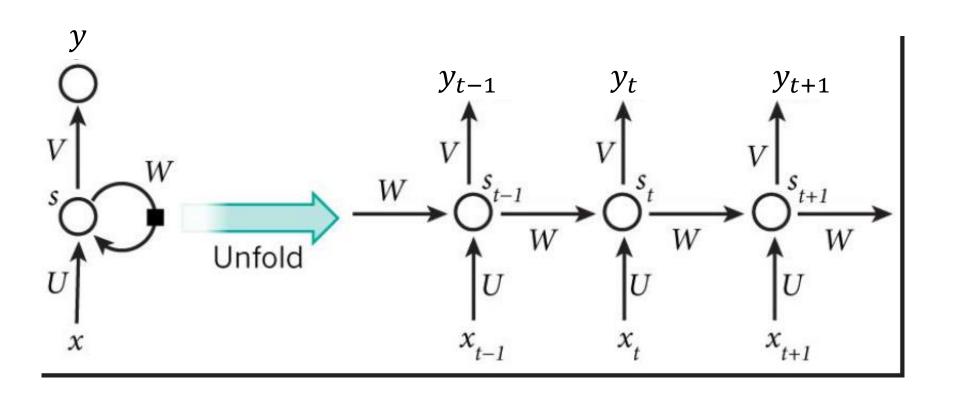

Input

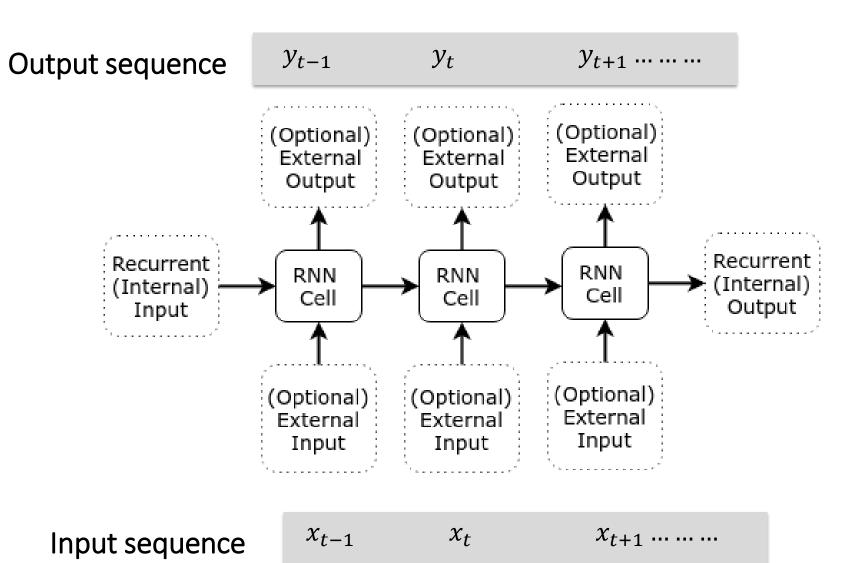

Here is the algebraic description of the RNN cell:

$$\left(egin{array}{c} s_t \ o_t \end{array}
ight) = f\left(egin{array}{c} s_{t-1} \ x_t \end{array}
ight)$$

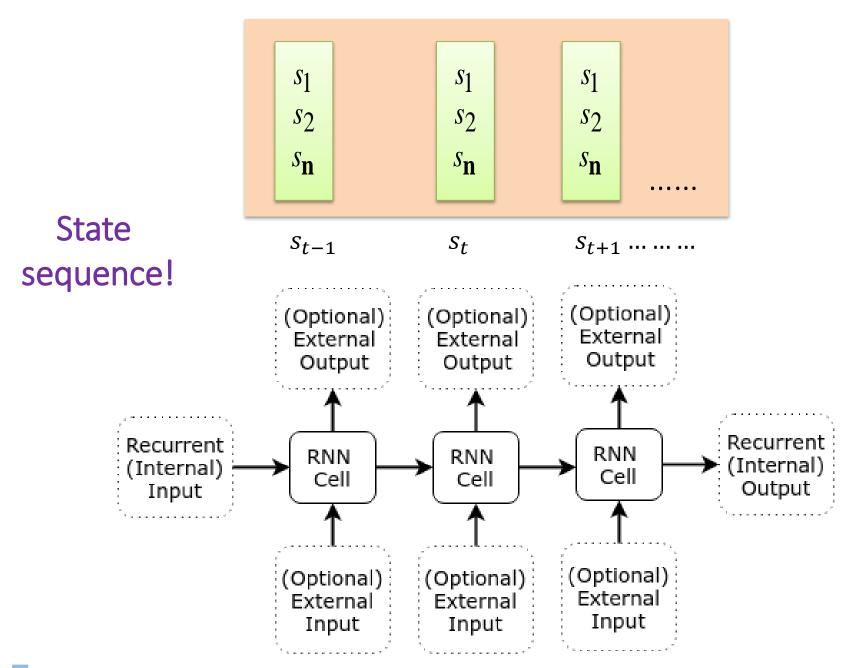

where:

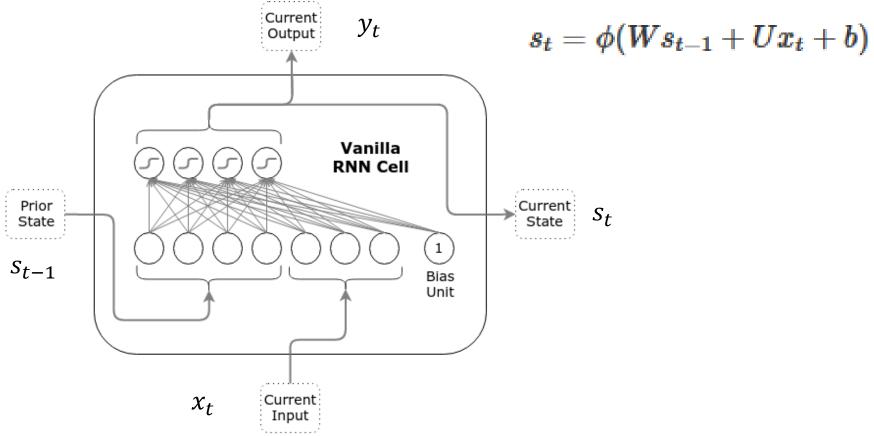

- s_t and s_{t-1} are our current and prior states,
- o_t is our (possibly empty) current output,
- x_t is our (possibly empty) current input, and
- *f* is our recurrent function.

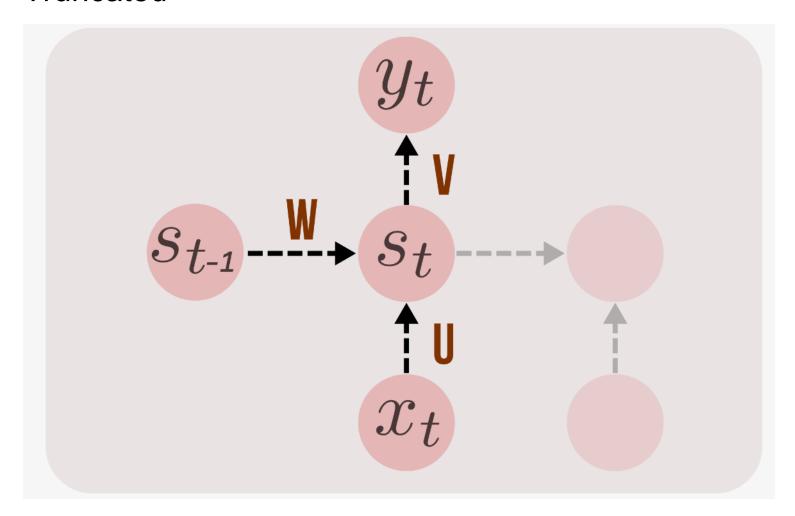

where:

- ϕ is the activation function (e.g., sigmoid, tanh, ReLU),
- $s_t \in \mathbb{R}^n$ is the current state (and current output),
- $s_{t-1} \in \mathbb{R}^n$ is the prior state,
- $x_t \in \mathbb{R}^m$ is the current input,
- $W \in \mathbb{R}^{n \times n}$, $U \in \mathbb{R}^{m \times n}$, and $b \in \mathbb{R}^n$ are the weights and biases, and
- n and m are the state and input sizes.

TRAINING RNN: W, U, V?

- BPTT: Backpropagation Through Time
- Truncated

Backpropagation Through Time (BPTT)

- Because the parameters are shared by all time steps in the network
- The gradient at each output depends not only on the calculations of the current time step, but also the previous time steps.

http://www.wildml.com/2015/09/recurrent-neural-networks-tutorial-part-2-implementing-a-language-model-rnn-with-python-numpy-and-theano/

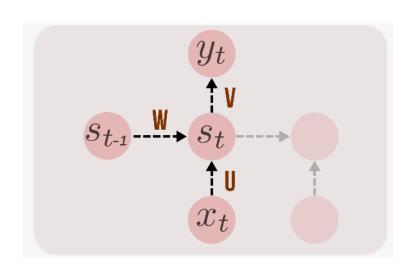

Backpropagation Through Time (BPTT)

$$s_t = \tanh(Ux_t + Ws_{t-1})$$

 $\hat{y}_t = \operatorname{softmax}(Vs_t)$

Cross entropy loss:
$$E(y, \hat{y}) = \sum_{t} E_t(y_t, \hat{y}_t) = -\sum_{t} y_t \log \hat{y}_t$$

- The output value does depend on the state of the hidden layer,
- which depends on all previous states of the hidden layer
- and thus, all previous inputs

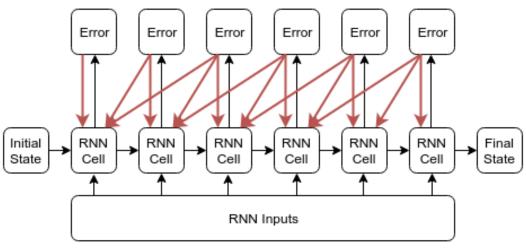

Backpropagation Through Time (BPTT)

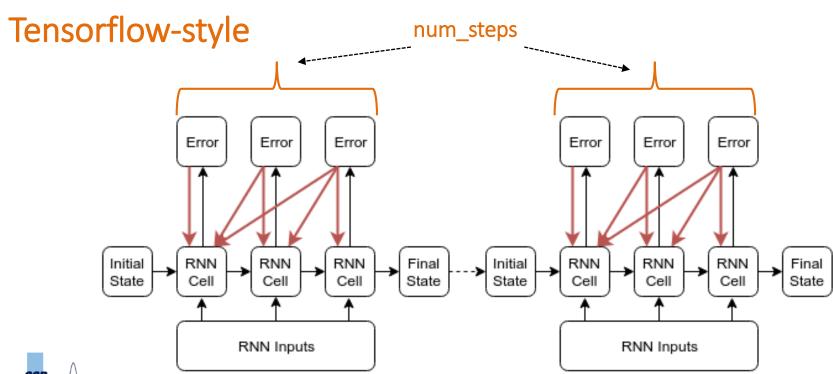

- But the recurrent net can be seen as a (very deep) feedforward net with shared weights
 - The forward pass builds up a stack of the activities of all the units at each time step.
 - The backward pass peels activities off the stack to compute the error derivatives at each time step.
 - After the backward pass we add together the derivatives at all the different times for each weight

$$\frac{\partial E_t}{\partial W} = \sum_{k=0}^{t} \frac{\partial E_t}{\partial y_y} \frac{\partial y_t}{\partial s_t} \frac{\partial s_t}{\partial s_k} \frac{\partial s_k}{\partial W} \xrightarrow{E_0} \underbrace{E_1}_{E_1} \underbrace{E_2}_{E_2} \underbrace{E_3}_{E_3} \underbrace{E_4}_{E_4}$$

Styles of Truncated Backpropagation

Vanishing gradient problem

In an RNN trained on long sequences (e.g. 100 time steps) the gradients can easily explode or vanish.

Led to the development of **LSTM**s and **GRU**s, two of the currently most popular and powerful models

http://www.wildml.com/2015/09/recurrent-neural-networks-tutorial-part-2-implementing-a-language-model-rnn-with-python-numpy-and-theano/

Let's practices for series prediction

in TensorFlow with a BasicRNNCell

https://github.com/MasterMSTC/DeepLearning_TF_Keras

MSTC_RNN_1_Series_2018.ipynb

Tensorflow RNN static vs. dynamic

- Tensorflow contains two different functions for RNNs: tf.nn.rnn and tf.nn.dynamic_rnn.
- Internally, tf.nn.rnn creates an unrolled static-graph for a fixed RNN length.
 - First, graph creation is slow.
 - Second, you're unable to pass in longer sequences than you've originally specified.
- tf.nn.dynamic_rnn solves this. It uses a tf.While loop to dynamically construct the graph when it is executed.
 - Graph creation is faster;
 - and you can feed batches of variable size.

Tensorflow RNN static vs. dynamic

What about performance? dynamic is faster?

In short, just use tf.nn.dynamic_rnn. There is no benefit to tf.nn.rnn and I wouldn't be surprised if it was deprecated in the future.

http://www.wildml.com/2016/08/rnns-in-tensorflow-a-practical-guide-and-undocumented-features/

Tensorflow RNN static vs. dynamic

rnn_inputs are different

rnn_inputs to tf.nn.rnn is a list of tensors

rnn_inputs to tf.nn.dynamic_rnn is:

A Tensor with dimension [batch_size, n_step, n_input]

See <u>Neural networks and deep learning by</u> <u>Aurélien Géro</u>

https://www.safaribooksonline.com/library/view/neural-networks-and/9781492037354/ch04.html

In particular Fig 9 to understand reshape

 You can try with financial data (hard) and synthetic signals (easy)

As well as with LSTM and GRU

Now let's try a simple NLP task

Predicting Text Characters

https://github.com/MasterMSTC/DeepLearning_TF_Keras

MSTC_Keras_RNN_2_Text_2018.ipynb

Text prediction & generation using RNN

Text Prediction/Generation with Keras using LSTM: Long Short Term Memory networks

In this example we will work with the book: Alice's Adventures in Wonderland by Lewis Carroll.

We are going to learn the dependencies between characters and the conditional probabilities of characters in sequences so that we can in turn generate wholly new and original sequences of characters.

Adapted from:

Text Generation With LSTM Recurrent Neural Networks in Python with Keras

By Jason Brownlee

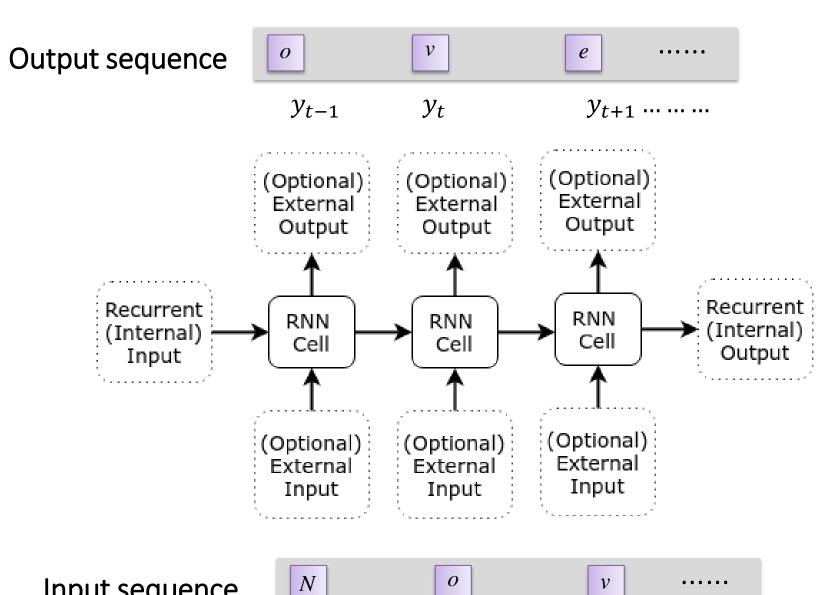

The NLP Task: language modeling to capture the statistical relationship among words / chars

The objective of the network is to observe the input *x*, one character at a time and produce the output sentence *y*, one character at a time

X (string)	Y (string)

Andrej Karpathy, Blog on "Unreasonable Effectiveness of Recurrent Neural Networks"

Basic concepts: LSTM & GRU

http://colah.github.io/posts/2015-08-Understanding-LSTMs/

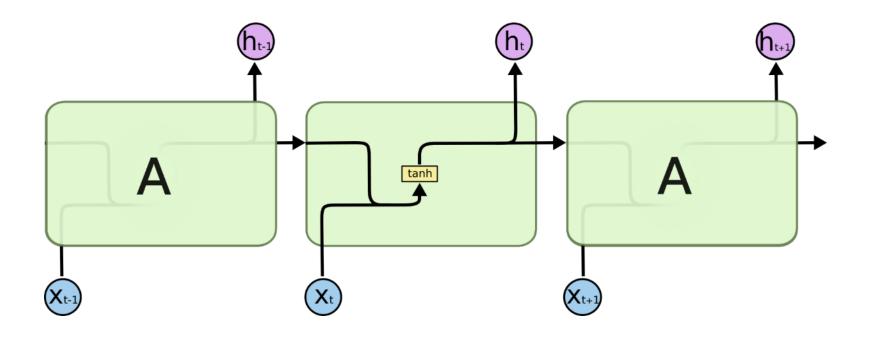

Vanishing gradients: a problem?

it may be that for some tasks we want gradients to vanish completely, and for others, it may be that we want them to grow

 Are RNNs capable of handling "long-term dependencies?"

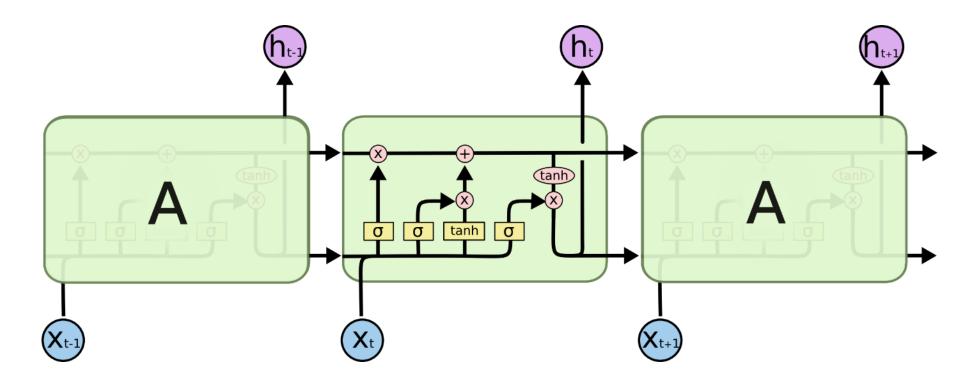

> Long Short Term Memory networks – LSTMs Hocreiter and Schmidhuber (1997)

The repeating module in a standard RNN contains a single layer

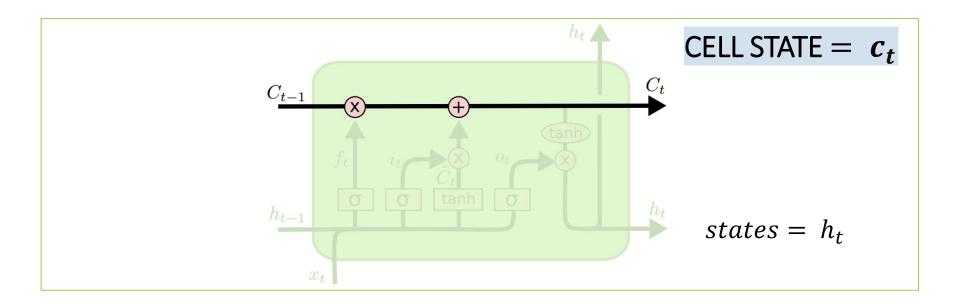

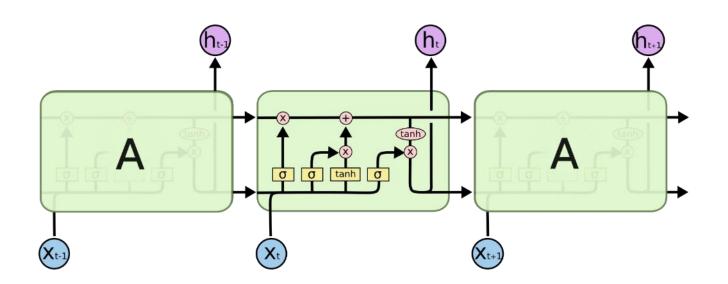

The repeating module in LSTM contains four interacting layers

Core Idea Behind LSTM

Tensorflow NOTE:

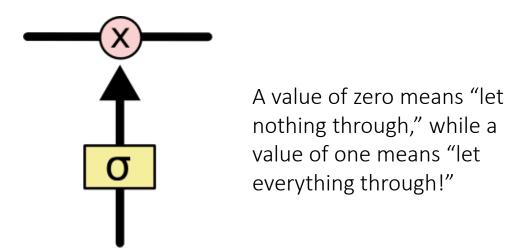

cell = tf.nn.rnn_cell.LSTMCell(state_size, state_is_tuple=True)

• "Hidden State" h_t and "Cell State" , \mathcal{C}_t

Core Idea Behind LSTM

- The LSTM does have the ability to remove or add information to the cell state, carefully regulated by structures called gates.
- Gates are a way to optionally let information through.
- They are composed out of a sigmoid neural net layer and a pointwise multiplication operation.

An LSTM has three of these gates, to protect and control the cell state

Basic concepts: LSTM & GRU

Hocreiter and Schmidhuber (1997)

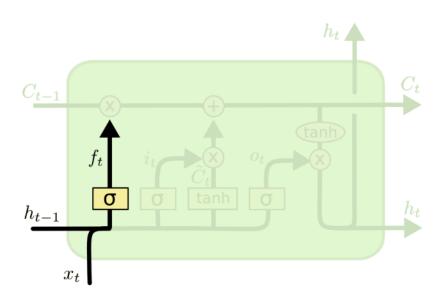

- The fundamental principle of LSTMs: to ensure the integrity of our messages in the real world, we write them down
- The fundamental challenge of LSTMs and **keeping our state** under control is to be selective in three things:
 - 1. what we write (write selectivity),
 - 2. what we read (because we need to read something to know what to write) (read selectivity)
 - 3. and what we forget (because obsolete information is a distraction and should be forgotten) (forget selectivity)

Gates as a mechanism for selectivity

Forget gate: The first step in our LSTM is to decide what information we're going to throw away from the cell state.

When we "see" something new relevant we decide forget....

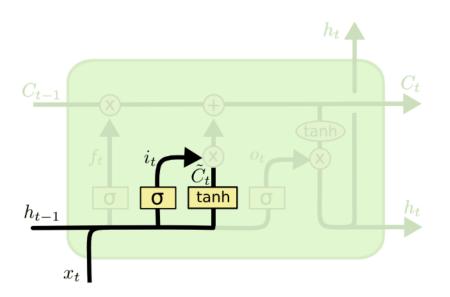

$$f_t = \sigma\left(W_f \cdot [h_{t-1}, x_t] + b_f\right)$$

The next step is to decide what new information we're going to store in the cell state. This has two parts.

- First, a sigmoid layer called the "input gate layer" decides which values we'll
 update.
- Next, a **tanh layer** creates a vector of new candidate values, \widetilde{C}_t , that could be added to the state.

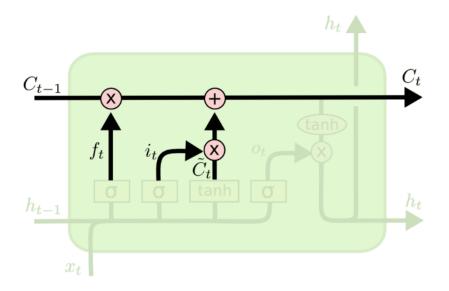

$$i_t = \sigma \left(W_i \cdot [h_{t-1}, x_t] + b_i \right)$$

$$\tilde{C}_t = \tanh(W_C \cdot [h_{t-1}, x_t] + b_C)$$

It's now time to update the old cell state, C_{t-1} , into the new cell state C_t

- The previous steps already decided what to do, we just need to actually do it.
- We multiply the old state by f_t (forget gate) then we add $i_t * \tilde{\mathcal{C}}_t$

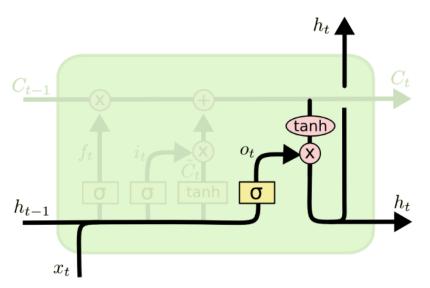

$$C_t = f_t * C_{t-1} + i_t * \tilde{C}_t$$

Finally, we need to decide what we're going to output h_t . This output will be based on our cell state, but will be a filtered version.

- First, we run a sigmoid layer which decides what parts of the cell state we're going to output.
- Then, we put the cell state through tanh (to push the values to be between −1 and 1) and multiply it by the output of the sigmoid gate, so that we only output the parts we decided to.

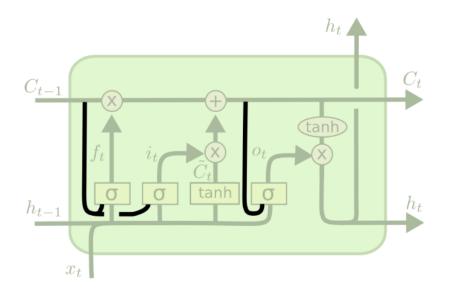

$$o_t = \sigma(W_o [h_{t-1}, x_t] + b_o)$$
$$h_t = o_t * \tanh(C_t)$$

One popular LSTM variant, introduced by Gers & Schmidhuber (2000), is adding "peephole connections."

This means that we let the gate layers look at the cell state.

$$f_{t} = \sigma \left(W_{f} \cdot [\boldsymbol{C_{t-1}}, h_{t-1}, x_{t}] + b_{f} \right)$$

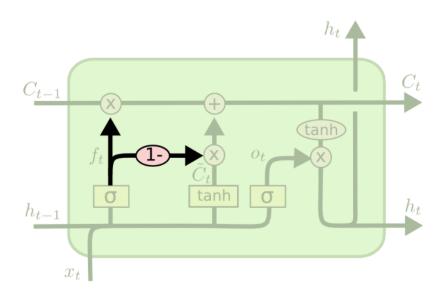

$$i_{t} = \sigma \left(W_{i} \cdot [\boldsymbol{C_{t-1}}, h_{t-1}, x_{t}] + b_{i} \right)$$

$$o_{t} = \sigma \left(W_{o} \cdot [\boldsymbol{C_{t}}, h_{t-1}, x_{t}] + b_{o} \right)$$

The above diagram adds peepholes to all the gates, but many papers will give some peepholes and not others.

Another variation is to use coupled forget and input gates.

• We only input new values to the state when we forget something older

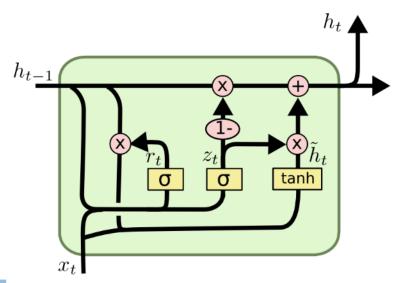

$$C_t = f_t * C_{t-1} + (1 - f_t) * \tilde{C}_t$$

Gated Recurrent Unit, or GRU, introduced by Cho, et al. (2014).

- It combines the forget and input gates into a single "update gate."
- It also merges the cell state and hidden state, and makes some other changes.

The resulting model is simpler than standard LSTM models, and has been growing increasingly popular.

$$z_{t} = \sigma (W_{z} \cdot [h_{t-1}, x_{t}])$$

$$r_{t} = \sigma (W_{r} \cdot [h_{t-1}, x_{t}])$$

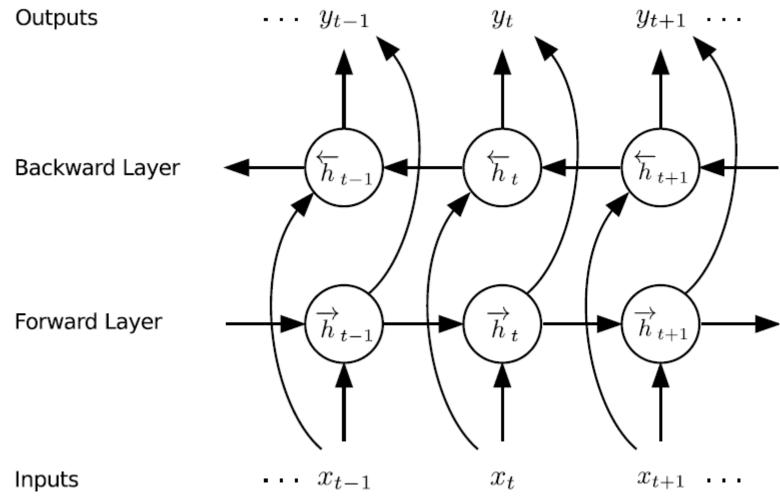

$$\tilde{h}_{t} = \tanh (W \cdot [r_{t} * h_{t-1}, x_{t}])$$

$$h_{t} = (1 - z_{t}) * h_{t-1} + z_{t} * \tilde{h}_{t}$$

These are only a few of the most notable LSTM variants.

See for example: **BLSTM** Bi-directional LSTM

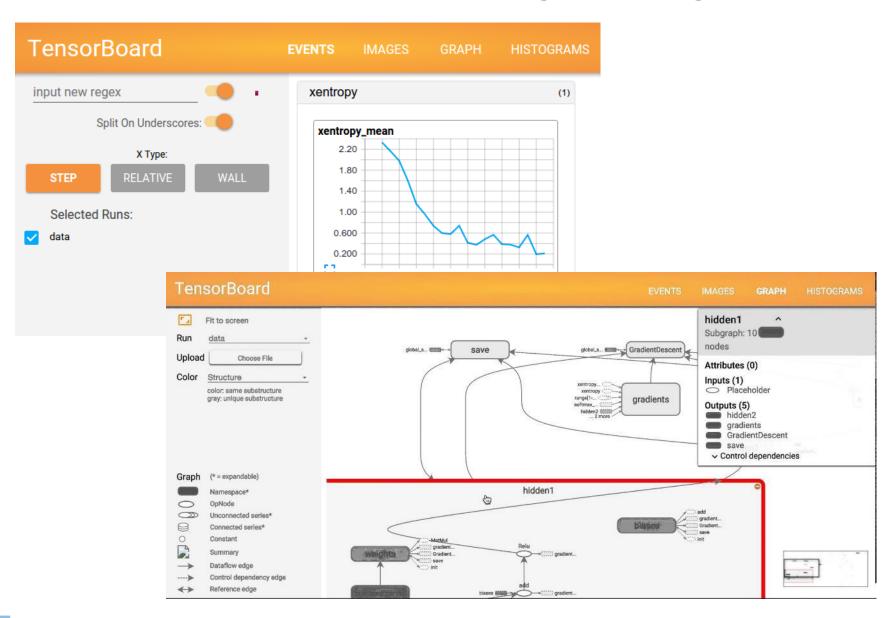

Which of these variants is best? Do the differences matter?

- Greff, et al. (2015) do a nice comparison of popular variants, finding that they're all about the same.
- Jozefowicz, et al. (2015) tested more than ten thousand RNN architectures, finding some that worked better than LSTMs on certain tasks.

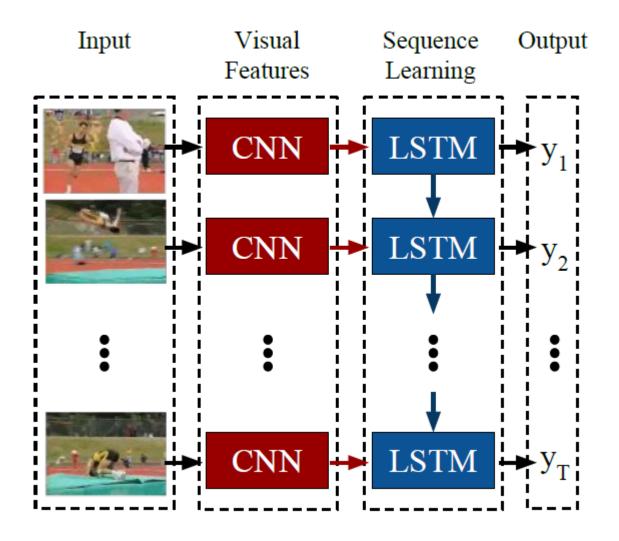

TensorBoard: Visualizing Learning

Remember you can combine different DL architectures

...sometimes CNNs are considered as feature extraction after RNN...

..for Eric Martín...

https://www.dukascopy.com/fxcomm/fx-article-contest/?Automated-High-Frequency-Trading-With=&action=read&id=1835

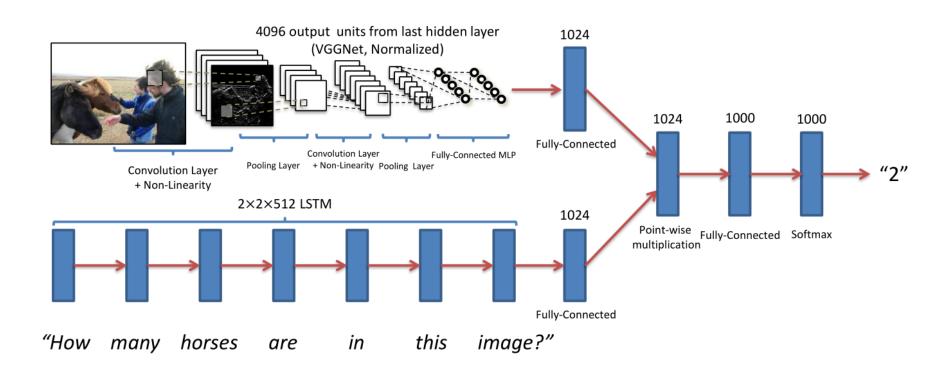

With the LSTM we don't need to use any indicator because it's going to build its own indicators that are totally hidden from us.

We only need to feed it the past tick to tick movements, one at a time, over the period we've chosen and it will predict the following movement.

Remember you can combine different DL architectures

...sometimes CNNs and RNNs are combined for modelling different multimodal sources...

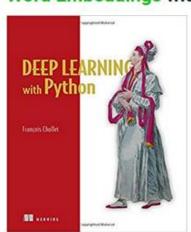

Embedding:

Indices by themselves, carry no semantic meaning

https://github.com/MasterMSTC/DeepLearning_TF_Keras

MSTC_Keras_RNN_3_Word_Embeddings_2018.ipynb

Word Embeddings with Keras
